Overview

This project proposes a car maintenance tracking and recommendation app that helps vehicle owners manage and maintain their cars. By tracking routine services like oil changes and tire rotations, the app provides condition-based recommendations to prevent costly repairs and extend vehicle lifespan.

Project Goals

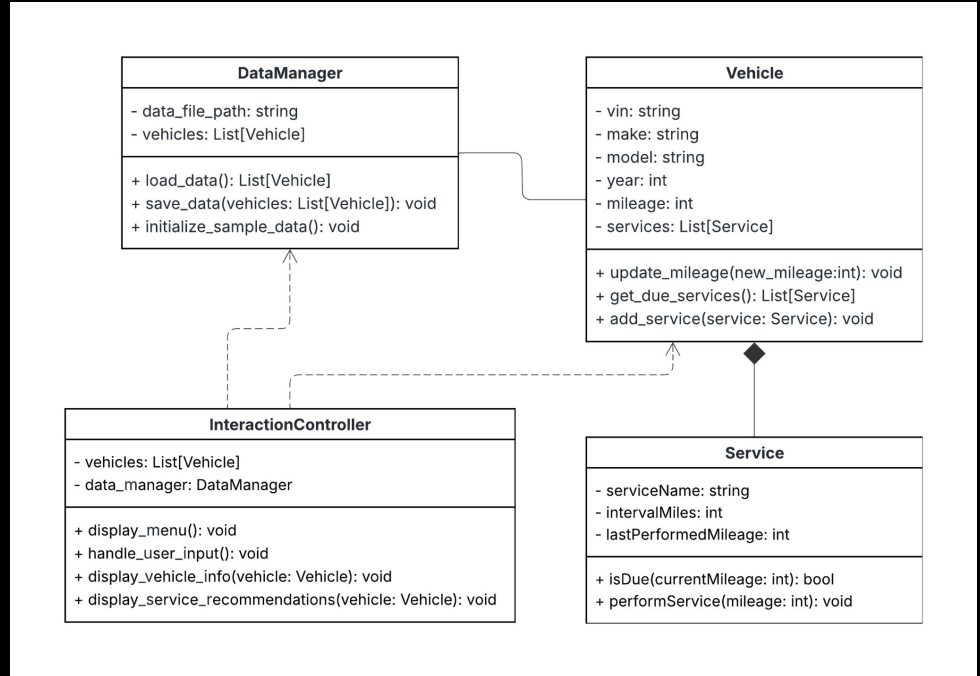

In addition to maintenance recommendations, the app allows users to log services, track mileage, and monitor upcoming or overdue tasks. It also helps users find nearby mechanics, connecting maintenance records with local service providers.

Features of the MVP

The MVP will focus on tracking basic vehicle data and simulating maintenance needs using sample records. Users can manage vehicles with mileage, service history, and health indicators, receiving recommendations for services like oil changes and brake inspections. All data will be internally generated, allowing core system development without external integrations.

Customer Feedback

- "There isn't input validation. For example, if I entered 'Year: abc' the program crashes. Or if I type 'Select vehicle index: 999' sometimes it handles it and sometimes it doesn't."
- "The mileage logic isn't explained. In the dashboard, I see 'OK', 'Due Soon', and 'Overdue' but I don't know what the threshold is, what 'soon' means, or what rule triggered it."
- "When I edit mileage or make it says updated, but I don't see the new full vehicle details. I'd expect it to reprint the updated vehicle."
- "Logging a service doesn't validate the date. If I enter 'Service data: banana' it'll likely break when parsed later."
